

Code Challenge

Use the WordPress REST API and Angular to build a simple decoupled website. WordPress will be the backend, Angular the frontend and communication between the two will be through the WordPress REST API.

The site will consist of a:

- home page that displays:
 - a banner image controlled from the WordPress admin.
 - a list of blog posts along with a thumbnail image for each.
- blog post page for individual blog posts. Featured image, post date should be displayed.
- Include a readme.md file that documents how to get the site running locally.

Notes

- Blog posts can be Lorem Ipsum. Don't worry about creating content for this site. Five or six blog posts will do.
- Responsive layout will be a plus, but keep it simple. The site design will not be a part of this challenge. Image placeholders will be fine.

Delivery

Please deliver the source code in a single Github repository that includes:

- The Angular frontend code
- The WordPress backend code
- Install instructions in README to run the code locally

Bonus points for having the site hosted on some cloud infrastructure setup.
